Deep Dive! Clean Architecture in .NET
Validations

Model Validation in Presentation/Application Layer
Business Validation in Domain Layer
Example: Age Field in User Model
  Age > 0 presentation
  Age > 18 domain layer (business rule)
Model Validation = Validating user input against
certain criteria before processing it
You can either throw an exception or create
a value object that wraps int age.
Third option is Fluent Validation rules
Validators usually go on the command objects
  in the application layer

Domain Events
 An option vs. normal orchestration patterns.
 Various Event Handlers that handle relevant events

Transactional Consistency - Change handled as a whole.
  Low Cognitive load, Simple, Performance loss
    Limited Error Handling, Low Scalability
Eventual Consistency - change is divided
  High Cognitive load, Complex, Highly performant
  Flexible error handling, Scalability
  ,

Subcutaneous Testing - Tests that run right
  under the presentation layer
